ABSTRACT: Background: This study was conducted to examine the physiological mechanisms involved in alleviating the detrimental effects of heat stress on broiler chickens by supplementing drinking water with licorice extract (LE). Methods: A total of 600 one day old broiler chicks were used. Birds have been assigned to 4 treatment groups with 3 replicates of 50 chicks each (150 chicks per treatment). Birds in the first treatment (T1) were provided drinking water alone and considered as a control group. Birds in treatments 2 (T2), 3 (T3) and 4 (T4) were provided drinking water supplemented with 150, 300 or 450 mg LE/liter, respectively. Hematological traits included in this study were: Erythrocyte counts (RBC), hemoglobin concentration (Hb), thrombocyte counts (Thr), leucocyte counts (WBC), heterophil/lymphocyte ratio (H/L ratio), hematocrit (pcv) and plasma levels of uric acid (Uri), glucose (Glu), cholesterol (Cho), Protein (Pro), aspartate aminotransaminase activity (AST), alkaline phosphatase activity (ALP), calcium (Cal) and phosphorus (Pho). Results: It was found that inclusion of LE in the drinking water of broiler chickens exposed to heat stress resulted in significant (p < 0.05) increases in RBC, Hb, Thr, WBC, PCV, and plasma Uri, Glu, AST, ALP, Ca and Pho and significant (p < 0.05) decreases in H/L ratio, and plasma Cho and Pro compared with T1. T4 recorded the best results with relation to all blood characteristics included in this experiment. Conclusions: It was concluded from this study that supplementation of LE (particularly at the level of 450 mg/liter) to the drinking water of broiler chickens can depress the adverse effects of heat stress on general physiological status.

INTRODUCTION

Licorice is a perennial herb native to Asia, the Mediterranean region and southern Europe. Licorice is one of the most popular herbs worldwide, used for both medicinal and culinary purposes. Historically it has been used as a sweetener, and medicinally as an antibacterial, anti-tumor, anti-viral, fungicidal, anti-inflammatory, anti-stress, anti-diabetic, antioxidant agent, and for adrenal insufficiency and stomach and intestine problems. The active components are glycyrrhizin, glycyrrhetic acid, flavonoids, isoflavones and triterpenoid saponins. One of the active constituents, glycyrrhizin has a similar structure as the adrenal steroid hormones. This may explain its potential role in ameliorating the resistance of body to stress factors. Davis and Morris reported that certain constituents found in licorice are expected to enhance the adrenal gland more smoothly in conditions of stress and exhaustion. The adrenal gland is the source of hormones that keep the body systems balanced. Naturopaths have used licorice in treating hypoglycemia, diabetes and Addison’s disease, which is a malfunction of the adrenal gland.

Each summer, broiler chicken producers face the challenge of avoiding heat stress in their birds. Acute heat waves often come unexpectedly and many birds are lost. Long periods of hot weather cause poultry to perform below their expected targets. Producers must pay close attention to feeding and management to maintain flock health, livability, uniformity, and get the best productive performance. Siegel demonstrated that heat stress caused adrenocortical insufficiency and a significant
decline in levels of plasma corticosteroids. A change in levels of blood glucose, protein, cholesterol, uric acid and some enzymes concluded to be related to these hormonal changes, was also recorded. Stormer et al. reported that where stress is a major factor, supporting the nervous system with herbal nervines and adaptogens such as licorice may be the best approach. An attempt has therefore been made to determine the effect of heat stress alone, and its modification by supplementing drinking water with LE on hematological traits of broiler chickens.

MATERIALS AND METHODS

A total of 600 one day old broiler chicks were reared on floor pens. Chicks were distributed at random among four treatment groups with three replicates per treatment, with 50 chicks per replicate. The ad libitum dietary regimen consisted of starter diet containing 22.7% crude protein and 3067.4 K cal ME/kg of diet (0 to 3 wk) and a finisher diet containing 20.6% crude protein and 2922 K cal ME/kg of diet (4 to 8 wk). Birds in the first group (T1) provided drinking water alone and considered as a control group, while birds in treatments 2 (T2), 3 (T3) and 4 (T4) received drinking water supplemented with 150, 300 or 450 mg LE/liter, respectively.

At the third week of age, birds in all treatments were exposed to heat stress (38 – 43°C) for 6 hours daily (1200h – 1800 h). The period of heat exposure was continued until the end of experiment (8th week of age). Gas brooders were used as a source of heat exposure in the experimental house. However, the supplementation of LE to the drinking water of birds was also started at the third week of age and continued until 56 day of age. At the end of experiment (8 weeks of age), blood samples were collected into a tube (containing heparin) by brachial vein puncture of 30 birds in each treatment. The hematological characteristics evaluated in the present experiment and which have shown to indicate general physiological status of birds consisted of the following (method in parenthesis): Erythrocyte counts – RBC, hemoglobin concentration – Hb, thrombocyte counts – Thr, leukocyte counts – WBC, heterophil to lymphocyte ratio – H/L ratio, hematocrit – PCV and plasma uric acid – Uri, plasma glucose – Glu, cholesterol – Cho, protein – Pro, aspartate aminotransaminase activity – AST, alkaline phosphatase activity – ALP, calcium – Cal, and phosphorus – Pho.

Data were subjected to an ANOVA using the General Linear Models (GLM) procedure of SAS. Significant treatment means were separated by using the multiple range test of Duncan.

RESULTS AND DISCUSSION

Results revealed that birds exposed to heat stress and provided drinking water supplemented with LE had significantly (p < 0.05) higher RBC, Hb, Thr, WBC, and PCV values than birds provided drinking water with no added LE (Table 1). Significant increases in these trait values were obtained with increasing LE level. T4 recorded the highest means in regards to these characteristics in comparison with all other treatments included in this experiment. These results may because licorice has properties similar to corticosteroids and ACTH hormones. Hence it may have a role in the reinforcement of body to stress. Armanini et al. reported that by acting as a blood purifier and enhancer, licorice cleanses the blood as well as enhances its' cells by increasing the nutrient value of food material within the body. By enhancing corticosteroids activity, glycyrrhizin helps to increase energy, ease stress, and reduce the symptoms of ailments sensitive to corticosteroid levels, such as chronic fatigue syndrome and fibromyalgia. In the 1800s, LE was a common remedy for a type of persistent fatigue known as neurasthenia, the condition now known as chronic fatigue syndrome. Modern research on LE has reported effects including: adrenal enhancement, anti allergic effects, blood cell enhancement (both red and white), bone marrow enhancement, anti-inflammatory effects, antioxidant activity, central nervous system depressant activity and immune potentiating effects. Oliff reported that licorice can help reduce inflammation. It appears to prevent the breakdown of adrenal hormones such as cortisol (the body's primary stress – fighting adrenal hormone), making these hormones more available to the body. Licorice also appears to enhance immunity by increasing WBC via stimulate their production in production sites in the body and by boosting levels of interferon, a key immune system chemical that fights of attacking viruses.

Addition of LE to the drinking water of broiler chickens caused a significant (p < 0.05) decrease in H/L ratio compared with control group (Table 1). Furthermore, T4 recorded the lowest value for this trait in comparison with the other LE doses. Gross and Siegel reported that the H/L ratio measures physiological changes, whereas the concentration of corticosteroids in the blood is affected by many factors before physiological changes occur. Therefore the H/L ratio should be a better measure of long – term changes in the environment, and the
concentration of corticosteroids in the blood should be a better measure of short-term changes. Therefore, the H/L ratio is a good measure of the chicken’s perception in its environment, and increasing H/L ratio indicated that the birds were under acute stress.\(^{27}\)

Plasma Uri, Glu, Pro, and AST exhibited differences among treatment groups (Table 2). Plasma Uri, Glu, and AST were higher while plasma Pro was lower in LE treatments (T2, T3 and T4) than control group (T1). Siegel\(^{[6]}\) reported that of the many effects attributed to corticosteroids, the most fundamental are those on metabolic processes. Corticosteroids increase plasma Glu and enhance glycogenolysis. The gluconeogenesis is presumably from labile Pro as is indicated by an increase in non-protein nitrogen, a decrease in the incorporation of Glu carbon into Pro, a decrease in plasma Pro and an increase in Uri excretion . The higher corticosteroid level resulted in significant (p < 0.05) increased by LE treatment activity in chicken during stress may be due to the inactivation of aldosterone – keto acids produced.\(^{\alpha-keto acids produced}\)

\(\alpha\)-keto acids produced are important source of substrate for gluconeogenesis.\(^{29}\) However, Baker\(^{[30]}\) reported that glycyrhetic acid, the steroid like constituent of glycyrhizic acid, inhibits an enzyme responsible for inactivating corticosteroid in the kidney. Treatment with licorice essentially extends the lifetime of corticosteroids and hence enhances the resistance of body to stress. Siegel\(^{[6]}\) reported that if the stressor continues to be strong and persistent and no escape is possible, the bird will enter the stage of exhaustion when its adrenals lose their ability to sustain glucocorticoid production and the result may be physical disability and death. Our results also revealed that the addition of LE to the drinking water of broiler chickens resulted in significant (p < 0.05) decreases in plasma Cho compared with control group (Table 2). Furthermore, T4 recorded the lowest value for this trait in comparison with other treatments used in the present study. This result may be explained by the hypocholesterolemia property of licorice.\(^{[31]}\) Bensky and Gamble\(^{[32]}\) reported that in China, LE was traditionally used as anti-asthmatic, anti-inflammatory, aldosterone–like and cortisone enhancing, anti-ulcer and blood cholesterol lowering actions. Licorice has been shown to reduce low density lipoprotein and cholesterol. The active components of licorice inhibit the formation of lipid peroxides and protect low density lipoprotein associated carotenoids.\(^{[33]}\) Compared to control group, plasma ALP, Cha, and Pho were significantly (p < 0.05) increased by LE treatments (T2, T3 and T4; Table 2). The improvement in these traits in our study in birds treated with LE may be a result of LE suppressing or limiting the damaging effects of stress.\(^{[4]}\) Al – Daraji et al.\(^{[34]}\) found that treated broiler chickens exposed to heat stress with probiotic or LE resulted in significant improvement in mean body weight, feed conversion ratio, cumulative weight gain, livability, Productive Index (PI), Economic Figure (EF) and dressing percentage as compared with control group and potassium chloride and sodium bicarbonate treatments. Moreover, LE treatment surpasses probiotic treatment with respect to mean body weight, weight gain, cumulative feed consumption, livability and dressing percentage. Hoffman reported that licorice is one of the group plants that have a marked effect upon the endocrine system.\(^{[35]}\) The glycosides present have a structure that is similar to the natural steroids of the body. This study hypothesizes that this similarity results in the beneficial actions of licorice in counteracting the deleterious effects of stress and in the treatment of adrenal gland problems. Both licorice extract and glycyrrehetic acid are shown to have deoxycorticosterone and ACTH–like effects, although with less toxicity than cortisone, encouraging its use as an anti–stress agent.\(^{[36]}\) Studies have shown that glycyrhizin stimulates the excretion of hormones by the adrenal cortex. Previous research has suggested it as possible drug to prolong the action of cortisone. Glycyrrhizin has

**CONCLUSIONS**

In conclusion, hematological traits were significantly affected by heat stress exposure. The addition of LE to the drinking water significantly recovered the adverse effects of heat stress on hematological parameters of broiler chickens. The protective effect of 450 mg LE / liter (T4) used in this experiment against the noxious effects of heat stress was greater than that of 150 (T2) and 300 mg LE / liter (T3). These improvements in blood characteristics could contribute to a solution of heat stress problem in broiler chickens.
