**ABSTRACT**

**Introduction:** The methanolic extracts and its different partitioning fractions of leaves of Clerodendrum indicum were evaluated for their anti-nociceptive, anti-diarrheal and in vitro antimicrobial activities. **Methods:** The anti-nociceptive activity was evaluated using the acetic acid-induced writhing test in mice; the anti-diarrheal activity was investigated by the effect of extracts on castor oil-induced diarrhea while the in vitro antimicrobial activities were examined by the disc diffusion method. **Results:** In the acetic acid-induced writhing test, the methanolic extract at a dose of 200 and 400 mg/kg showed a significant (p<0.001) and dose-dependent reduction in the number of writhes with 62.57% and 70.76% of inhibition, respectively, while the CCl₄ fraction at the same dose showed potent anti-nociceptive activity (p<0.001) with 73.09% of inhibition of writhing which was even higher than that of standard diclofenac sodium (55.56% inhibition). The methanolic extract, CCl₄ and chloroform fraction showed moderate activity against the tested microorganisms in terms of both zones of inhibition (ranged from 9-13 mm, 10-13 mm and 10-13 mm, respectively, at a concentration of 400 μg/disc) and spectrum of activity. In castor oil-induced diarrhea testing, the methanolic extract and chloroform fraction at a dose of 400 mg/kg produced 21.74% and 26.96% inhibition of defecation, respectively, which were found to be comparable to that of standard drug loperamide (37.39% inhibition at 50 mg/kg) with regard to the severity of diarrhea. **Conclusion:** The results of the investigation demonstrated that the methanolic extract and its different fractions of leaves of Clerodendrum indicum possess significant anti-nociceptive, antimicrobial and antidiarrheal activities.

**Key words:** Clerodendrum indicum; leaves; anti-nociceptive; antimicrobial; anti-diarrheal; writhing

**INTRODUCTION**

Since ancient times, medicinal plants have been used for the treatment and management of various health problems. About 80% of the world’s population relies on the use of traditional medicine, which is predominantly based on herbal products.[1] To ensure the rational use of herbal medicine, it is imperative to validate the folkloric claim of medicinal plants used in traditional medicine so that the beneficial ones can be deployed as phytomedicines and the bioactive constituents from such beneficial plants could be isolated and used as “leads” in drug discovery process.[2]

Clerodendrum indicum (family: Verbenaceae; vernacular names: Bamunhatti, Nuli gach) is an annual shrub which is found in areas with moderate temperature. The species occurs variably in India, Nepal, Myanmar, Malaya, Indo-China, Indonesia, Java and Bangladesh. Leaves (aerial parts) and roots of Clerodendrum indicum are used for various medicinal purposes. In traditional system of remedies, the plant is mainly used in the treatment of asthma, bronchitis, cold fever, intestinal worms, arthritis, epilepsy, febrile convulsion, gastric tumor, hematuria, hysteria, impotence, lipoma, nasal polips, painful micturation and rheumatism.[3-5] Paste made out of its leaves is effective in application on wounds for early healing,

and healing of the infected lymph node (lymphadenopathy). Leaf powder is used in digestive disorders and other GI-related ailments. It purifies blood, improves blood circulation and suppresses all kind of swelling of the body. It acts on the respiratory system thus expelling out the excessive mucus in the tract relieving cough, cold and asthma symptoms.

Although the leaves of the plant have been traditionally used in the treatment of various painful and anti-inflammatory conditions, gastrointestinal disorders and infectious disease, there is no extensive anti-nociceptive, antimicrobial and anti-diarrheal study of this valuable medicinal plant. Only Raihan et al. reported the analgesic activity of crude ethanolic extract of leaves and Rahman et al. reported the in vitro antibacterial activity of root and stem of the plant previously. To prove the ethno-medical claims, the present study was designed to evaluate the anti-nociceptive and anti-diarrheal activities of the methanolic extracts and its different partitioning fractions of leaves of Clerodendrum indicum in mice model. The in vitro antimicrobial activities of the methanolic extracts and its different partitioning fractions of leaves were also investigated.

MATERIALS AND METHODS

Chemicals and reagents
The chemicals used were: acetic acid (Merck, Germany), castor oil (Sigma Chemicals, USA), diclofenac sodium and loperamide (Square Pharmaceuticals Ltd; Dhaka, Bangladesh), normal saline solution (0.9% NaCl; Orion Infusion Ltd, Bangladesh), Dimethylsulfoxide and Tween-80 from Sigma–Aldrich and rests of the chemicals used were of BDH and E-Merk analytical grade.

Preparation of plant sample
Leaves of Clerodendrum indicum were collected from Modhupur, Tangail, Bangladesh, in November 2009 and authentication of the sample was confirmed by the taxonomist of the National Herbarium of Bangladesh, Mirpur, Dhaka. A voucher specimen no. has been deposited (accession No: DACB 34556) in the Herbarium for further reference. The leaves were sun dried for several days. After complete drying, the dried leaves were then ground to a coarse powder using high capacity grinding machine in the Phytochemical Research Laboratory, Faculty of Pharmacy, University of Dhaka. The coarse powder was then stored in an airtight container marked for identification and kept in a cool, dark and dry place for future use.

Extraction and partitioning of the plant material and sample preparation
About 900 gm of powdered leave material was taken in a clean, round bottomed flask (5 liters) and macerated at room temperature in 3 liters of methanol for 10 days with occasional shaking for better extraction. The whole mixture was then filtered through cotton followed by Whatman’s No. 1 filter paper. After filtration, the filtrate was concentrated at 40 °C with a Heidolph rotary evaporator. The concentrated extract was then air dried to a solid residue. The weight of the crude methanolic extract of leaves obtained was 56 gm. Fractionation of the methanolic extracts was carried out by using solvent-solvent partitioning using the protocol designed by Kupchan and modified version by Wagenen. The crude extract (35 gm) was dissolved in 10% aqueous methanol which was subsequently extracted with petroleum ether, carbon tetrachloride and chloroform. All the three partitioning (pet ether fraction, carbon tetrachloride fraction and chloroform fraction) fractions were evaporated to dryness by using rotary evaporator and kept in airtight containers for further analysis. The extracts and standard drug (diclofenac sodium, loperamide) were suspended in normal saline using 0.1% Tween-80.

Experimental animals
Swiss-albino mice (Mus musculus) of either sex, aged 4-5 weeks, obtained from the Animal Resource Branch of the International Center for Diarrheal Diseases and Research, Bangladesh (ICDDR, B) were used for the experiment. They were housed in polypropylene cages (30x20x13 cm) and kept in standard environmental conditions (temperature 23 ± 2 °C, relative humidity 55 ± 10% and 12 hours light/dark cycle). The animals were fed with standard rat food (ICDDR, B formulated) and water ad libitum. As these animals are very sensitive to environmental changes, they were kept in the environment where the experiment would take place 7 days before the test. The design and performance of research study involving mice was approved by the Ethical Review Committee, Faculty of Biological Science, University of Dhaka through the submission of a research protocol before the study.

Experimental procedures
Acetic acid-induced writhing response in mice
The methanolic crude extract and the different fractions of the methanolic extract of the leaves of Clerodendrum indicum were subjected to a screening for analgesic activity by acetic acid-induced writhing inhibition method. Initially, the Swiss albino mice were divided into five groups (n=5). Subsequently, vehicle (1% Tween-80 solution in normal saline, 10 ml/kg, as control group), diclofenac sodium (50 mg/kg, as standard), methanolic crude extract (200 and 400 mg/kg) and CCl₄ fraction of methanolic extract (200 mg/kg) were administered orally by means of a long needle with a ball-shaped end. After 40 minutes, acetic acid (0.7%, 0.1 mL/10 g) was administered intra-peritoneally to each of the animals of all the groups to induce pain. A forty-minute interval between the oral administration
of test materials and intra-peritoneal administration of acetic acid was given to assure proper absorption of the administered samples. Five minutes after the administration of acetic acid, the number of squirms or writhing characterized by contraction of the abdominal musculature together with turning of trunk and extension of hind limbs, were counted for each mouse for fifteen minutes. Percentage inhibition of writhing in comparison to control group was taken as an index of analgesia and was calculated using the following formula:

\[
\text{Inhibition (\%)} = \left( \frac{W_c - W_t}{W_c} \right) \times 100
\]

Where \(W_c\) is the average number of writhing reflex in the control group and \(W_t\) is the average number of writhing in the test groups.

**In vitro Antimicrobial Screening**

The *in vitro* antimicrobial activities of methanolic crude extracts and its different fractions from *Clerodendrum indicum* leaves were examined by the disc diffusion method.\[11-14\] The bacterial and fungal strains used for the experiment were collected as pure culture from the Institute of Nutrition and Food Sciences (INFS), University of Dhaka. A measured amount of each test sample (methanolic crude extract, pet-ether fraction, chloroform fraction and \(\text{CCl}_4\) fraction) was dissolved in a specific volume of the solvent (chloroform) to obtain the desired concentrations and applied to sterile discs (6 mm diameter) at a concentration of 400 μg/disc followed by drying off the solvent in an aseptic hood. Discs containing the test material were placed on nutrient agar medium uniformly seeded with the test microorganisms. Standard antibiotic Kanamycin (30 μg/disc) discs and blank discs (impregnated with 10 μl of solvents) were used as positive and negative controls, respectively. These plates were then kept at a low temperature (4 °C) for 24 hours to allow maximum growth of the organisms. The test materials were dissolved and diffused out of the sample disc. The plates were then incubated at 37 °C for 24 hours to allow maximum growth of the organisms. If the test materials have any antimicrobial activity, it will inhibit the growth of the microorganisms and a clear, distinct zone of inhibition will be visualized surrounding the medium. The antimicrobial activity of the test agent was determined by measuring the diameter of zone of inhibition expressed in millimeter. The experiment was carried out in duplicate.

**Effect of extract on castor oil-induced diarrhea**

The effect of the methanolic crude extract and its different solvent-soluble fractions on castor oil-induced diarrhea was evaluated by the method described by Uddin et al.\[15\] and Awouters et al.\[16\] In this method castor oil is used to induce diarrhea in all the experimental groups. The defecation is the primer to measure the anti-diarrheal effect. Thirty experimental mice were randomly selected and divided into six groups consisting of 5 mice in each group. Group I received vehicle (1% Tween-80 solution in normal saline, 10 ml/kg, as control group) and Group II received the standard anti-diarrheal agent loperamide (50 mg/kg p.o.). The third, fourth, fifth and sixth groups were the test groups and received methanolic crude extract and pet ether, \(\text{CCl}_4\) and chloroform fractions of methanolic extract, respectively at a dose of 400 mg/kg body weight p.o. Prior to any treatment, each mouse was weighed properly and the doses of the test samples and control materials were adjusted accordingly. Each animal was then given 0.5 ml of castor oil orally after 30 min of treatment and placed in transparent cages to observe for consistency of fecal matter and frequency of defecation for 3 h. Feces were collected with an absorbent sheet of paper placed beneath the transparent cages.\[17\] The wet feces were read at the end of the experiment by lifting up the upper part of the cage containing the sheet of paper and animals. The percent (\%) inhibition of defecation was measured using the following formula.

\[
\text{% Inhibition of defecation} = \left( \frac{(A - B)}{A} \right) \times 100
\]

\(A\) = Mean number of defecation caused by castor oil or extract

\(B\) = Mean number of defecation caused by drug

**Statistical analysis**

The results obtained were expressed as mean ± SEM. The data were analyzed using one-way analysis of variance (ANOVA) followed by Dunnett’s *t* test to determine the level of significance. A value of *P*<0.05 was considered to be significant. The statistical analysis was carried out using the SPSS program (version 17).

**RESULTS**

**Acetic acid-induced writhing response**

In the acetic acid-induced writhing test, the methanolic crude extract of leaves of *C. indicum* at a dose of 200 and 400 mg/kg body weight showed a significant (*p*<0.001) and dose-dependent reduction in the number of writhes with 62.57% and 70.76% of inhibition, respectively (Table 1) when compared to the control which were even higher than that of the standard drug diclofenac sodium (55.56% inhibition; *p*<0.001). The carbon tetrachloride fraction of the crude extract at a dose of 400 mg/kg also showed potent anti-nociceptive activity (*p*<0.001) with 73.09% of inhibition of writhing response when compared to control.
**In vitro antimicrobial screening**

The zones of inhibition produced by methanolic crude extract, carbon-tetrachloride fraction and chloroform fraction of the methanolic extract of *Clerodendrum indicum* (leaves) ranged from 9-13 mm, 10-13 mm and 10-13 mm, respectively at a concentration of 400 μg/disc (Table 2). The methanolic crude extract, carbon-tetrachloride fraction and chloroform fraction showed moderate activity against the tested organisms in terms of both zone of inhibition and spectrum of activity against some gram-positive, gram-negative bacteria and fungi. But the pet ether fraction showed no antimicrobial activity.

### Screening of antidiarrheal activity

The chloroform fraction of the crude extract exhibited significant anti-diarrheal activity, while the methanolic crude extract exhibited moderate anti-diarrheal activity (Table 3). The percent of inhibition of defecation produced by the chloroform fraction of the crude extract was 26.96%, while methanolic crude extract showed 21.74% inhibition at a concentration of 400 mg/kg body weight. The results were found to be comparable to that of standard drug loperamide.

The intraperitoneal administration of a 0.7% solution of saponins, alkaloids and tannins are known to have curative antimicrobial activities. It has been documented that the methanolic extract and its CCl₄ fraction and pet-ether soluble fraction of the methanolic crude extract exhibited poor antidiarrheal activity having 15.65% and 17.39% inhibition of defeation, respectively, at a concentration of 400 mg/kg body weight.

DISCUSSION

The writhing response of the mouse to intraperitoneally injected noxious chemicals such as acetic acid is widely used to screen for peripheral analgesic activity.[18] The intra-peritoneal administration of a 0.7% solution of acetic acid induces endogenous pain mediators, such as prostaglandins, histamine and bradykinin, which stimulate the pain sensation locally.[19] It has been reported that the level of prostanooids, particularly PGE₂ and PGF₂α, as well as lipooxygenase products significantly increased in the peritoneal fluid during writhing test.[20-21] The ability of the extracts to attenuate the pain induced writhing in mice suggests that they possess analgesic activity. So the observed analgesic activity of the methanolic crude extracts and carbon-tetrachloride fraction of the plant might be due to its possible interference in the biosynthesis, release and/or action of some chemical agents such as prostaglandins and leukotrienes from cyclo-oxygenase and lipooxygenase pathway, respectively, which are mainly responsible to block the pain sensation and thereby showed pain-inhibitory activity. Phytochemical study of ethanolic extracts of leaves of Clerodendrum indicum revealed the presence of saponins, steroid, saponin, tannin etc.[10] The presence of steroids, saponins and tannins may be major contributors to the anti-nociceptive activity as previously it has been observed that tannins, saponins and steroidal compounds possess good analgesic activity by inhibiting prostaglandin synthesis.[22-23]

The data from the in vitro antimicrobial screening test showed that the methanolic extract and its CCl₄ and chloroform partitionates showed moderately potent and broad spectrum antimicrobial activities. It has been documented that saponins, alkaloids and tannins are known to have curative activity against several pathogenic bacteria and fungus.[24] The broad antibacterial activities of the leaf extracts of Clerodendrum indicum might be due to the presence of these compounds (saponins, alkaloids and tannins).

Castor oil-induced diarrheal model is widely used for the evaluation of anti-diarrheal property of drugs. The anti-diarrheal property of the methanolic crude extract and chloroform fraction of methanolic extract of Clerodendrum indicum leaves found in the present study could be owing to the presence of tannins, alkaloids, saponins and terpenes.[25-27]

CONCLUSION

In conclusion, the results of this study demonstrated that the methanolic extract and different partitioning fractions of leaves of Clerodendrum indicum possess significant anti-nociceptive, antimicrobial and anti-diarrheal activities. The findings of the study validated the traditional use of the plant in the treatment of different painful conditions, gastro-intestinal disorders and infectious diseases. Further works are required to isolate and characterize the bioactive compound(s) responsible for the observed analgesic, antimicrobial and anti-diarrheal activities and to evaluate the mechanism(s) of action of these activities.
